Bind observations and record feedback

Scenario: task-feedback / workflow-map. Candidate based on main 48b854b, captured 2026-10-18. Use Python 3.11+ with a disposable home and synthetic project. Default installations collect nothing.

1. Find the task commands

Open docs/map/workflow.html. Under Self-improvement and eval, open Private observations and expand its details. Follow Sources to account/observation/README.md for the command contract.

Actual map dialog. Task selections and feedback exist; Codex collection and case export remain planned in this slice.

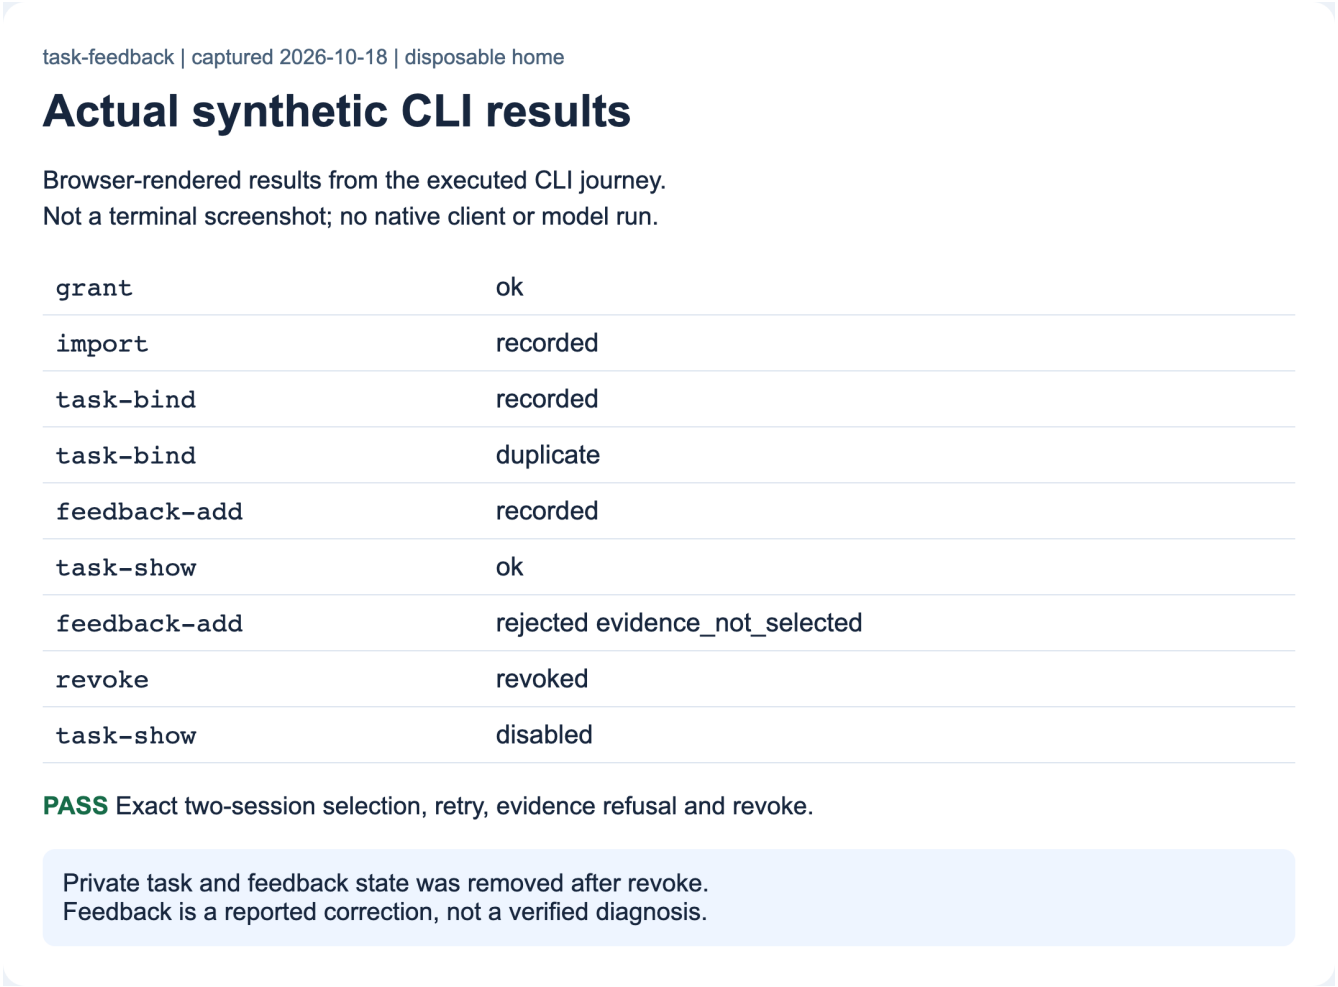

Expected result: Use task-bind to freeze exact events or an inclusive receipt range. Use feedback-add for a symptom and correction, and task-show to inspect the private revision.

Bind observations and record feedback

Scenario: task-feedback / workflow-map. Candidate based on main 48b854b, captured 2026-10-18. Use Python 3.11+ with a disposable home and synthetic project. Default installations collect nothing.

2. Select, review and revoke

Grant a disposable synthetic project and import events from two sessions. Bind only the intended events, repeat the request to check idempotency, then add feedback and inspect task-show. Reject unselected evidence. Revoke the grant when finished.

Selected output from the actual CLI smoke, rendered in a browser. This is not a terminal capture or native/model qualification.

Expected result: The exact selection stays frozen. Retry returns duplicate; unselected evidence is rejected. After revoke, task-show returns disabled and private task/feedback records are removed.
